Empirical project 2 of 36

#### 1 Idea

We want to look at the relationship between certain prices and the respective search interest on Google for these prices. Can we find granger causality for this relationship? What are possible issues? For example: modern trading algorithms scrape data from the internet and then buy or sell based on the sentiment. Large spikes in search interest may trigger such algorithms. As media spreads the news of price increases more people will look up prices of goods and commodities, again triggering the algorithms. This is basically a feedback loop.

#### 2 Data

First some notes on the data. The data on the search index of certain prices is taken from Google trends which collects the search queries of people within a specific region (here: United States of America). This data is aggregated on a monthly basis and normalized with a range from zero to 100. Already filtered out are duplicate searches in the sense that the same user made the same search multiple times within a short time-frame. This way we exclude the users which have already invested and constantly checked the prices to look how their investment is doing. Data points are divided by total searches for the month and region to represent the relative popularity, i.e. no over-weighting of regions with more people than others which would, given the same search behavior, lead to differing popularities otherwise.

The data on gold prices comes form the London Bullion Market Association Gold Price and the Federal Reserve Bank of St. Louis. It is measured in USD per troy, daily at 3:00pm. Aggregation is done via prices at the end of each month and it is not seasonally adjusted.

In parts of this project we scale the price and search index to a range from zero to one in order to compare the relative movements more easily.

## 3 Project Code

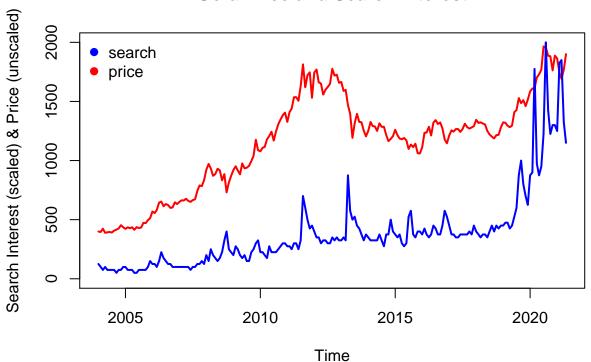

```
# clear workspace
rm(list=ls())
# load needed libraries
library(readr)
library(vars)
library(tseries)
# set working directory
#setwd("/Users/samue/Downloads/Studium/Economics (Master - Vienna)/2. Semester/Macroeconometrics/Projec
# import search trends
data <- read_csv("btc-vs-gold-2004.csv", col_types = cols(Month = col_date(format = "%Y-%m")))</pre>
# import prices data:
gold pr <- read csv("gold-2004.csv", col types = cols(DATE = col date(format = "%Y-\%m-\%d")))</pre>
# import high-frequency prices for gold:
gold HF <- read csv('gold-2001-HF.csv', col types = cols(DATE = col date(format = '%Y-%m-%d'),GOLDPMGBD
# plot gold price on monthly basis
plot(y=gold_pr$GOLDPMGBD228NLBM,x=gold_pr$DATE,type = '1', lwd = 2, col = 'red',
```

ylim = c(0,2000), main = 'Gold Price and Search Interest',

Empirical project 3 of 36

#### **Gold Price and Search Interest**

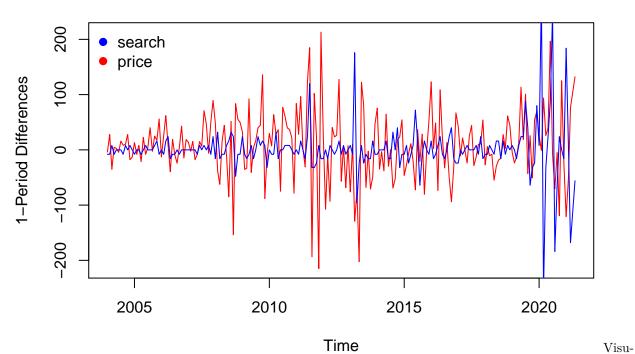

```
# create first differenced prices and search interest
t <- length(gold_pr$DATE)
gold_price_FD <- rep(0,t-1)</pre>
for(i in 2:209){gold_price_FD[i-1] <- gold_pr$GOLDPMGBD228NLBM[i]-gold_pr$GOLDPMGBD228NLBM[i-1]}</pre>
gold_search_FD <- rep(0,t-1)</pre>
for(i in 2:209){gold_search_FD[i-1] <- data$GOLD[i]-data$GOLD[i-1]}</pre>
t_1 <- length(gold_HF$DATE)</pre>
gold_daily_FD <- rep(0,t_1-1)</pre>
for(i in 2:5332){gold_daily_FD[i-1] <- gold_HF$GOLDPMGBD228NLBM[i]-gold_HF$GOLDPMGBD228NLBM[i-1]}</pre>
# plot first differenced variables
plot(y=gold_price_FD,x=gold_pr$DATE[1-209], type = 'l', lwd = 1, col = 'red',
     xlab = 'Time', ylab = '1-Period Differences',
     main = 'First Differences: Gold Price and Search Interest')
lines(y=gold search FD*8,x=gold pr$DATE[1-209], lwd = 1, col = 'blue')
legend('topleft', legend = c('search', 'price'),
       col = c('blue', 'red'), bty = "n", pch = c(19,19))
```

Empirical project 4 of 36

#### First Differences: Gold Price and Search Interest

ally, it appears that the more volatile periods match. An issue seems to be the scaling of the variables.

```
# plot ACF for unmodified variables:
par(mfrow=c(2,2))  # changes the plot layout to more easily compare them
acf(gold_pr$GOLDPMGBD228NLBM, main = 'ACF Gold Price')
acf(data$GOLD, main = 'ACF Gold Search Interest')

# plot PACF for unmodified variables:
pacf(gold_pr$GOLDPMGBD228NLBM, main = 'PACF Gold Price')
pacf(data$GOLD, main = 'PACF Gold Search Interest')
```

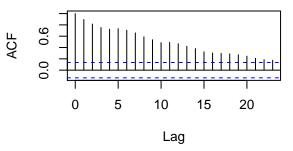

Empirical project 5 of 36

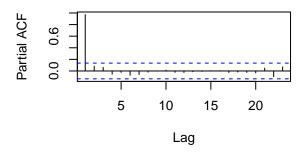

#### **ACF Gold Price**

#### 

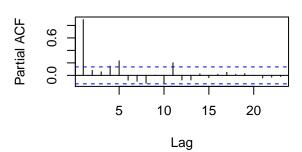

#### **ACF Gold Search Interest**

## **PACF Gold Price**

#### **PACF Gold Search Interest**

```
# plot ACF for differenced variables
acf(gold_price_FD,main = 'ACF Gold Price FD')
acf(gold_search_FD, main = 'ACF Gold Search Interest FD')

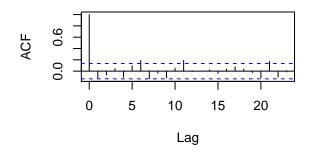

# plot PACF for differenced variables
pacf(gold_price_FD,main = 'PACF Gold Price FD')
pacf(gold_search_FD, main = 'PACF Gold Search Interest FD')
```

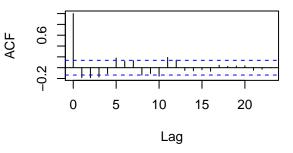

Empirical project 6 of 36

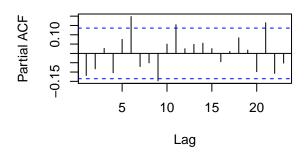

#### **ACF Gold Search Interest FD**

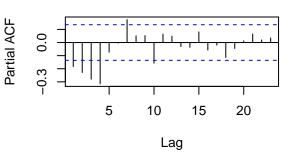

#### **PACF Gold Price FD**

#### **PACF Gold Search Interest FD**

```
par(mfrow = c(1,1)) # revert layout changes
```

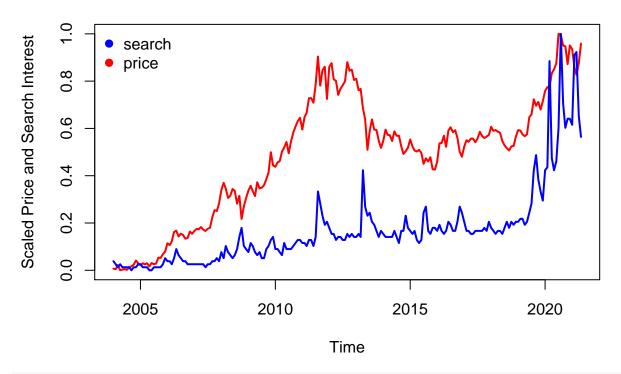

Autocorrelation for the differenced variables seems like no month-on-month relationship between the changes. Kind of like a random walk?

Might help with the interpretation: scale all variables **X** such that  $X_t \in [0,1] \forall t \in T$ .

```
range01 <- function(x){(x-min(x))/(max(x)-min(x))}
plot(y=range01(gold_pr$GOLDPMGBD228NLBM),x=gold_pr$DATE, lwd = 2, type = 'l',
    ylab = 'Scaled Price and Search Interest',
    xlab = 'Time', col = 'red')
lines(y=range01(data$GOLD),x=gold_pr$DATE, lwd = 2, col = 'blue')
legend('topleft', legend = c('search','price'),
    col = c('blue','red'), bty = "n", pch = c(19,19))</pre>
```

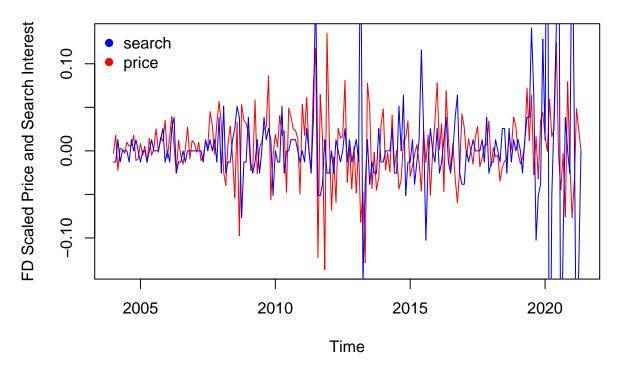

Empirical project 7 of 36

```
# save scaled variables
gold_price_scaled <- rangeO1(gold_pr$GOLDPMGBD228NLBM)</pre>
gold_search_scaled <- range01(data$GOLD)</pre>
# create first difference on scaled variables:
gold_search_scaled_FD <- rep(0,t-1)</pre>
gold_price_scaled_FD <- rep(0,t-1)</pre>
for(i in 2:t-1){
  gold_price_scaled_FD[i-1] <- gold_price_scaled[i]-gold_price_scaled[i-1]</pre>
for(i in 2:t-1){
  \verb|gold_search_scaled_FD[i-1]| <- \verb|gold_search_scaled[i]-gold_search_scaled[i-1]|
# plot first differenced:
plot(y=gold_price_scaled_FD, x=gold_pr$DATE[1-209], lwd = 1, type = '1',
     ylab = 'FD Scaled Price and Search Interest',
     xlab = 'Time', col = 'red')
lines(y= gold_search_scaled_FD, x=gold_pr$DATE[1-209], lwd = 1, col = 'blue')
legend('topleft', legend = c('search', 'price'),
       col = c('blue', 'red'), bty = "n", pch = c(19,19))
```

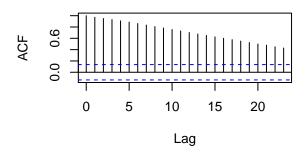

Empirical project 8 of 36

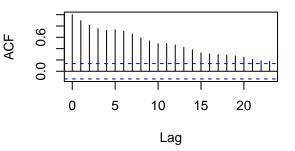

```
# plot ACFs
par(mfrow=c(2,2))  # changes the plot layout to more easily compare them
acf(gold_price_scaled, main = 'ACF Scaled Gold Price')
acf(gold_search_scaled, main = 'ACF Scaled Gold Search Interest')
acf(gold_price_scaled_FD, main = 'ACF Scaled Gold Price FD')
acf(gold_search_scaled_FD, main = 'ACF Scaled Gold Search Interest FD')
```

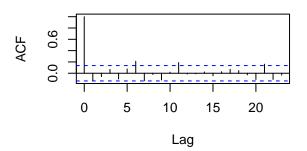

#### **ACF Scaled Gold Price**

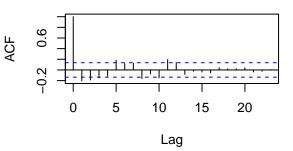

#### **ACF Scaled Gold Search Interest**

**ACF Scaled Gold Price FD** 

#### **ACF Scaled Gold Search Interest FD**

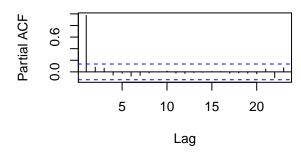

Empirical project 9 of 36

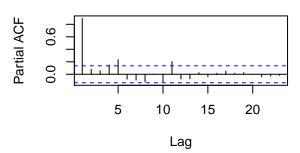

```
par(mfrow = c(1,1)) # revert layout changes

# plot PACFs
par(mfrow=c(2,2)) # changes the plot layout to more easily compare them
pacf(gold_price_scaled, main = 'PACF Scaled Gold Price')
pacf(gold_search_scaled, main = 'PACF Scaled Gold Search Interest')
pacf(gold_price_scaled_FD,main = 'PACF Scaled Gold Price FD')
pacf(gold_search_scaled_FD, main = 'PACF Scaled Gold Search Interest FD')
```

#### **PACF Scaled Gold Price**

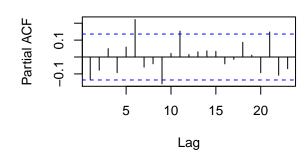

#### **PACF Scaled Gold Search Interest**

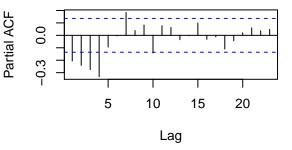

#### **PACF Scaled Gold Price FD**

#### **PACF Scaled Gold Search Interest FD**

```
par(mfrow = c(1,1)) # revert layout changes
```

Unsurprisingly the rescaling does not matter for the autocorrelation as it is a scaled measure of linear relationships anyway.

ACF Scaled Gold Search Interest FD together with PACF Scaled Gold Search Interest FD gives evidence for an AR(4).

For the Gold Price it's as you say. Could be a MA(1), AR(1) or an ARMA.

Should we also do DF for gold\_search?

Empirical project 10 of 36

```
start = c(2004, 1), end = c(2021, 5))

For the price we cannot reject the null of a non-stationary process (the random walk with drift+trend is the null), seems to fit conventional wisdom on prices. For the search index we reject the null given the data.

For both, the null cannot be rejected given the data, the null is non-stationarity. Not very unexpected for prices, as they are often thought about as following a random walk and thus being non-stationary. But we can also look at difference-stationarity to check.

```

The last model is automated to difference such that the data is stationary, then the function finds the best forecasting model via the AIC. Here this would be an ARMA(0,1) model:

$$\widehat{\Delta \text{gold price}}_t = (7.1279) + \epsilon_t + (-0.1411)\epsilon_{t-1}$$
3.6766

## 4 Phillips-Ouliaris Cointegration Test

Q: Ist es richtig hier VAR\_data zu verwenden?

```
po.test(VAR_data, demean = TRUE, lshort = TRUE)

##
## Phillips-Ouliaris Cointegration Test
##
## data: VAR_data
## Phillips-Ouliaris demeaned = -19.431, Truncation lag parameter = 2,
## p-value = 0.06318
```

We cannot reject the null of the residuals being I(1). Thus we cannot rule out the case of a spurious or unbalanced regression. Note: as we only have one I(1) process and one non I(1) process this test makes no real sense.

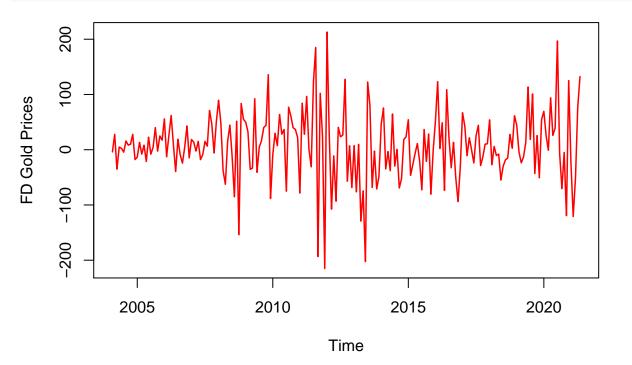

Sollten wir hier nicht mit MA(1) weiterarbeiten? Ich habs mal weiter unten mit MA(1) gemacht. Den AR(1) part aber noch nicht gelöscht
